

## CHAPTER – 5

### HYDROLOGY

#### 5.1 GENERAL

The hydrological studies of the Tarahn stream have been carried out in order to determine the optimum techno economic power potential of the site, to work out the design flood discharge and other related issues in respect of the Tranha Charroli HEP.

This chapter on hydrology deals with study of the hydro-Meteorological characteristics of the basin in the vicinity of the Tranha Charroli Small Hydro Power Project and the Methodology adopted for establishing various hydro-meteorological parameters which will form the basic inputs for project Planning and design purpose.

Keeping in view of the above, the hydrological investigation and analysis have been carried out for this project to

assess the feasible power generation by establishing a long-term series of average monthly discharge for the project site, study the hydraulic behavior of the stream regime and to establish design flood for the safe design of intake works.

### **5.2 CATCHMENT AREA**

Tarahn stream is the tributary of Sainj khad . The main source of Tarahn stream is the monsoon run-off as well as the run-off on account of snow melting. The elevation of catchment area of the Tarahn stream varies between 3600 meter to 1610 meter and it lies in the Shivalik ranges in Shimla Distt. of Himachal Pradesh. The entire catchment comprises mostly of mountainous terrain with steep hill slopes but generally of forest cover, being primarily a very less populated area. The flow of the Tarahn stream are low during Nov. to Feb. but starts increasing from February onwards with high flows during July to October due to monsoon rain fall.

It has a medium size fan-shaped catchment area of 14.71 Sq. km. up to the proposed diversion

weir. The index location map and catchment area map is enclosed.

### 5.3 PRECIPITATION

The precipitation in the catchment of Tarahn stream had take place in the form of snow & rain. The higher reaches experience snow fall whereas the lower reaches experience heavy rain during monsoon i.e. from June to Sep., which occasionally extends up to early October due to south west monsoon. Rain fall is negligible during winter and spring season (Oct. to march) which is generally due to western disturbance that pass over the North-West part of the country. During winter, the precipitation is either in the form of snow or rain depending upon the altitude & other metrological conditions.

### 5.4 SEDIMENT LOAD

This stream carries significant sediment load during monsoon consisting of silt and suspended particles. In the winter, water is quite clear and free from all kind of impurities.

However, design of the scheme will ensure that rolling bed load as well as silt does not enter the turbine. Intake has been designed to keep in check all floating substances and desilting tank has been designed so as to exclude silt particles greater than and up to 0.25 mm size with about 96% efficiency.

#### 5.5 STREAM FLOW DATA

Discharge observations have been recorded on Tarahn stream at Charroli village since January 2008 to March 2011. This data is available for two years. The discharge have been measured by float method and average ten daily observed data is appended in Annexure 5.1 for the above period.

#### 5.6 EXTENSION OF FLOW DATA

The present scenario presents a grim picture when it comes to planning of small/ mini hydro projects on account of non-availability of stream flow data over a long period. Records which are available are of short durations and do not meet the reliability index in as far as planning of such small projects are concerned.

Project planning and design necessitates at least ten years of historical data. It is also not feasible to collect data over such long periods for planning the project and therefore arises the need for estimation and extension of stream flow data..

It is therefore certain that meteorological characteristics of this project catchment resembles within acceptable limits, with those of Sainj Khad catchment. This data of Sainj Khad has been further reduced on catchment area basis for the establishing of run-of series to carry out preliminary hydrological and power studies in case of Tranh Charroli hydro power project. The average ten days daily discharges computed on catchment area basis w.e.f 1977 to 1983 and 2002 to 2005 has been shown in Annexure 5.3.

#### 5.7 DEPENDABLE YEAR

Diversion of Tranh Charroli small HEP has been designed to divert the flow by building diversion structures in the form of trench weir on the Tarahn stream. The net discharges from this stream are available for power generation

and as shown in Annexure 5.3 have been considered for carrying out power studies in respect of this project. As per CEA standing guidelines, for dependability analysis, the year-wise unrestricted energy generation from 1977 to 1983, 2002 to 2005 and 2008 to 2011, has been used by arranging the same in descending order. Based on data available as contained in Annexure- 5.3, analysis has been carried out to identify the 50%, 75% and 90% dependable years. The guidelines for establishing project capacities in respect of small hydro up to 25 MW requires to adopt the 75% dependable discharge, for this project, 75% dependable flows are considered. The results so obtained for identifying the dependable years are indicated in Annexure-5.4 to Annexure- 5.8

#### 5.7.1 CONSISTANCY OF FLOWS

It is necessary to establish the consistency of observed discharge at Sainj Khad site which is in vicinity of the proposed weir sites. The consistency check studies for flows may be carried out in either of the following two methods;

- i) Flow consistency with respect to rainfall,
- ii) Flow consistency with respect to discharge of other catchment.

An analysis of Discharge data of Sainj Khad with flow of Tarahn stream has been carried out to ascertain the degree of its co-relation. The results so obtained indicates an acceptable degree of consistency. Accordingly, it has been found that 1981 discharges have a 90% dependability, while the year 2005 has a dependability of 75%. However, for this project 75% dependability is being used for fixing the station capacity.

#### 5.7.2 CATCHMENT AREA

The catchment area of Tarahn stream at discharge site have been computed as below .

Tarahn Stream Charroli village (discharge site ) = 14.71 sq. km..

Sainj Khad upto Sainj  
= 135 sq. km.

$$\text{Modification Factor} = (14.71/135)^{3/4}$$

$$= 0.1896$$

## 5.8 DESIGN FLOOD DISCHARGE

### 5.8.1 DESIGN CRITERIA

The proposed diversion structure is a trench weir type. In the event of failure of such a structure, it would not cause any loss of life or damages to the properties downstream of the weir. A flood discharge due to a 50 year return period storm rainfall is considered sufficient. Design flood has been worked out by following methods :-

- i) Dicken's Empirical method.
- ii) Unit Hydrograph Method.

### 5.8.2 DESIGN FLOOD (BY DICKEN'S EMPIRICAL METHOD)

The catchment area of this Stream is very small i.e. 14.71 sq.km. and therefore, use of empirical formula has been made to access the design flood. The design flood for Tarahn Stream with 1 in 50

years probability works out to 105.16  
cumecs as computations below :

$$\text{Max. Flood Discharge } Q_{\max} = C \times A^{3/4}$$

$$\text{Catchment Area } A_w = 14.71 \text{ sq.km}$$

$$\text{Constant for hilly area 'C' } = 14$$

$$\text{Max.Flood Discharge } Q_{\max} = 14 \times (14.71)^{3/4}$$

$$= 105.16 \text{ cumecs}$$

### 5.8.3 DESIGN FLOOD ( BY UNIT HYDROGRAPH METHOD)

$$\text{Catchment area at Diversion site (A) } = 14.71 \text{ sq.km}$$

$$Q_{tp} = 1.747 \times (A)^{0.75}$$

Where

$Q_{tp}$  - Peak load discharge per cm of rainfall excess.

A ----- Catchment area in sq.km

$$Q_{tp} = 1.747 \times (14.71)^{0.75}$$

$$= 13.12 \text{ cumecs/cm}$$

$$t_c = 2.078 \times (A/Q_{tp})^{0.90}$$

$$= 2.078 \times (14.71/13.12)^{0.90}$$

$$= 2.30 \text{ hr.}$$

Design Flood = 50 years , 4 hours

Point rainfall = 80 mm

Area rainfall = 1.02 x 80

$$= 81.60 \text{ mm}$$

Peak of 50 years

Flood Hydrograph =  $Q_{tp} \times \text{Area rainfall}$   
 $= 13.12 \times 8.16$   
 $= 107.06 \text{ cumecs}$

#### 5.8.4 DESIGN FLOOD NEAR POWER HOUSE SITE

The tail race channel from the power house discharges into Tarahn Stream. This outfall point is about 3.5 km. downstream of the Tarahn Stream diversion weir site (along the river) , where the catchment area is 34.15 sq.km. The flood discharge  $Q_{max}$  at the weir site where the catchment area is 14.71 sq.km is
