

MODE OF TRANSPORT

The ROM Ore produced from the mines are transported by tippers to the processing yard. The ROM ore are broken, sized to 5mm-18mm, screened manually, to segregate the iron ore into two different marketable grade stacks. After the stacks are built up of required size and height, are sampled and assayed to ascertain its grade. Depending upon the grade of the stacks, the materials are transported by tippers and dumpers ranging in capacity from 10T to end use point for sales.
